

The Challenge: A Unified Inbox MVP

Imagine you're a property owner with properties managed by multiple letting services. You're juggling messages across all these platforms.

Build a web-based inbox that aggregates these messages in one place.

Requirements

- Browse a list of messages from all platforms
- Clearly show which service each message is from
- Click a message to view its content, plus associated property and booking details

API Design

The aggregation service doesn't exist yet - you'll need to mock it. Part of this exercise is thinking through what that API should look like:

- What endpoints would you need?
- What does the data structure look like?
- One API or multiple? Direct calls or a BFF pattern?

Document your reasoning.

Design

Your solution should feel professional, usable and consistent with our branding. We haven't provided mockups - part of this exercise is seeing how you make design decisions when specifications are, as they often are, incomplete. Use your judgement.

What We're Looking For

We expect about **2 hours of effort**. This is a first iteration, not a polished product. You're welcome to use whatever tools work for you (frameworks, design systems, AI tools, etc.).

Please document your thinking:

- **Assumptions:** What did you assume about users, data volumes, real-time needs?
- **Tool choices:** What frameworks/libraries/AI did you use and why? If you used LLMs, include your prompts
- **Architecture** How did you structure the data flow and API design?
- **Quality** How do you verify it works? What's your testing strategy?
- **Next steps** Given more time, what would you tackle next?

Include this in your README, code comments, or separate notes.
